CLAIMS

What is claimed is:

1. A method, comprising:

examining information about branch instructions that reach a write-back stage of processing within a processor;

defining a plurality of streams based on the examining, wherein each stream comprises a sequence of basic blocks in which only a last block in the sequence ends in a branch instruction, the execution of which causes program flow to branch, the remaining basic blocks in the stream each ending in a branch instruction, the execution of which does not cause program flow to branch.

- 2. The method of claim 1, further comprising storing identifying information for each defined stream.
- 3. The method of claim 2, wherein the identifying information comprises a start instruction pointer and an end instruction pointer for each stream.
- 4. The method of claim 1, further comprising collecting dependent information for each stream, the dependent information identifying a dependent stream, being a child stream that is executed after the stream during an instance of program execution, and the dependent information also indicating a probability of the dependent stream being executed after the stream.

- 5. The method of claim 4, further comprising predicting a target stream or block that is likely to be executed based on a current instruction pointer.
- 6. The method of claim 1, further comprising storing at least some of the basic blocks within a stream in contiguous memory locations.
- 7. The method of claim 1, further comprising converting at least some of the instructions in a stream into ISA-implementation specific instructions, and storing the ISA-implementation specific instructions in contiguous memory locations.
- 8. The method of claim 1, further comprising switching the processor between a stream mode in which instructions from a stream are prefetched based on the prediction and a normal mode in which instructions within a basic block are fetched based on the prediction.
- 9. A processor, comprising:

a mechanism to examine information about branch instructions that reach a write-back stage of processing within the processor; and

a mechanism to define a plurality of streams based on the examining, wherein each stream comprises a sequence of basic blocks in which only a last block in the sequence ends in a branch instruction, the execution of which causes program flow to branch, the remaining basic blocks in the stream each

ending in a branch instruction, the execution of which does not cause program flow to branch.

- 10. The method of claim 9, further comprising a mechanism to store identifying information for each defined stream.
- 11. The processor of claim 10, wherein the identifying information comprises a start instruction pointer and an end instruction pointer for each stream.
- 12. The processor of claim 9, wherein the mechanism to define the plurality of streams further collects dependent information for each stream, the dependent information identifying a dependent stream being a child stream that is executed after the stream during an instance of program execution, the dependent information also indicating a probability of the dependent stream being executed after the stream.
- 13. The processor of claim 12, wherein the mechanism to define the plurality of streams further comprises a prediction mechanism to predict a target stream or block that is likely to be executed based on a current instruction pointer.
- 14. The processor of claim 9, further comprising storing at least some of the basic blocks within a stream in contiguous memory locations.

- 15. The processor of claim 9, further comprising converting at least some of the instructions in a stream into ISA-implementation specific instructions, and storing the ISA-implementation specific instructions in contiguous memory locations.
- 16. The processor of claim 9, further comprising a mechanism to switch the processor between a stream mode in which instructions from a stream are prefetched based on the prediction and a normal mode in which instructions within a basic block are fetched based on the prediction.

17. A system, comprising:

a processor comprising a mechanism to examine information about branch instructions that reach a write-back stage of processing within the processor, and a mechanism to define a plurality of streams based on the examining, wherein each stream comprises a sequence of basic blocks in which only a last block in the sequences ends in a branch instruction, the execution of which causes program flow to branch, the remaining basic blocks in a stream each ending in a branch instruction, the execution of which does not cause program flow to branch; and

a memory coupled to the processor.

18. The system of claim 17, wherein the processor further comprises a mechanism to store identifying information for each defined stream.

- 19. The system of claim 18, wherein the identifying information comprises a start instruction pointer and an end instruction pointer for each stream.
- 20. A processor, comprising:
 - a fetch/prefetch unit;
- a branch prediction unit to supply a branch target address of a predicted branch based on a current instruction pointer to the fetch/prefetch unit; and

a stream prediction unit to supply a stream target address of a predicted stream based on a current instruction pointer to the fetch/prefetch unit, wherein the predicted stream comprises a sequence of basic blocks in which only a last block in the sequence ends in a branch instruction, the execution of which causes program flow to branch, the remaining basic blocks in the stream each ending in a branch instruction, the execution of which does not cause program flow to branch.

- 21. The processor of claim 20, wherein the stream prediction unit further comprises a mechanism to define a plurality of streams based on an examination of information about branch instructions that reach a write-back stage of processing within the processor.
- 22. The processor of claim 21, wherein the stream prediction unit further comprises a mechanism to store identifying information for each defined stream.

- 23. The processor of claim 22, wherein the identifying information comprises a start instruction pointer and an end instruction pointer for each stream.
- 24. The processor of claim 20, wherein the stream prediction unit comprises a mechanism that collects dependent information for each stream, the dependent information identifying a dependent stream being a child stream that is executed after the stream during an instance of program execution, the dependent information also indicating a probability of the dependent stream being executed after the stream.
- 25. The processor of claim 20, further comprising a mechanism to store at least some of the basic blocks within a stream in contiguous memory locations.
- 26. The processor of claim 20, further comprising a mechanism to convert at least some of the instructions in a stream into ISA-implementation specific instructions, and to store the ISA-implementation specific instructions in contiguous memory locations.

27. A system, comprising:

a processor comprising a fetch/prefetch unit, a branch prediction unit to supply a branch target address of a predicted branch based on a current instruction pointer to the fetch/prefetch unit, and a stream prediction unit to supply a stream target address of a predicted stream based on a current instruction pointer to the fetch/prefetch unit, wherein the predicted stream comprises a sequence of basic blocks in which only a last block in the sequence ends in a branch instruction, the execution of which causes program flow to branch, the remaining basic blocks in the stream each ending in a branch instruction, the execution of which does not cause program flow to branch; and a memory coupled to the processor.

- 28. The system of claim 27, wherein the stream prediction unit further comprises a mechanism to define a plurality of streams based on an examination of information about branch instructions that reach a write-back stage of processing within the processor.
- 29. The system of claim 28, wherein the stream prediction unit further comprises a mechanism to store identifying information for each defined stream.
- 30. The system of claim 29, wherein the identifying information comprises a start instruction pointer and an end instruction pointer for each stream.
